PATTERN GENERATION CIRCUIT, MULTI-PATH DETECTION CIRCUIT

EMPLOYING THE SAME AND MULTI-PATH DETECTION METHOD

BACKGROUND OF THE INVENTION

5   Field of the Invention

The present invention relates to a pattern generation circuit, a multi-path detection circuit employing the same and a multi-path detection method.   More particularly, the invention relates to a detection method of a multi-path position

10   for determining a reception timing of a finger of a RAKE receiver employed in a code division multiple access (CDMA) system (spread spectrum system).

Description of the Related Art

Conventionally, as a path timing detection circuit of

15   this kind, there is a circuit to be realized by measuring a delay profile of a propagation path by correlating operation of a reception signal and a spread code using a sliding correlator or matched filter and by detecting a correlation peak amount of the delay profile.

20   However, when intervals of respective multi-path is narrow, a plurality of paths can overlap on the delay profile to make it difficult to detect correct path position.

For example, in an example of the delay profile shown in Figs. 5A to 5C, when only one path is present, a shape of

25   the path has a width as illustrated in Fig. 5A.   On the other

hand, when a plurality of paths are present, if paths have enough interval as shown in Fig. 5, a plurality of paths can be identified.

However, when interval of the paths is small as shown in Fig. 5C, paths cause overlap to make it impossible to identify which sample point is the accurate path position. When the path position cannot be detected accurately, reception performance is degraded significantly.

In such case, in the prior art, it has been employed a method to set a minimum interval of respective finger position by omitting N samples (N is integer) before and after the detected path from next peak detection. Such method has been disclosed in "Path-Search Performance of DS-WCDNA System in Laboratory and Field Experiments" (Aoyama et al.: Technical Report of IEICE, RCS 97-164, 1997-11) (hereinafter referred to as publication 1)

However, in the foregoing method, it is required to preliminarily determine the minimum interval of the paths to detect. Also, in the foregoing method, the detected path position may be determined depending upon the set value to cause difficulty in detecting accurate timing.

Namely, in the foregoing publication 1, when the interval between the paths is narrow to overlap the paths, the N samples before and after the detected path are masked to omit from next peak detection, pseudo peak may appear in the pattern from which

the N samples before and after the detected path are omitted,
to cause difficult in detection of the accurate timing.

SUMMARY OF THE INVENTION

The present invention has been worked out in view of the

5   problems set forth above. It is therefore an object of the
present invention to provide a pattern generation circuit which
can enhance precision in detection of each path timing and thus
can obtain more stable reception performance, a multi-path
detection circuit and a multi-path detection method employing

10   the same.

According to the first aspect of the present invention,
a pattern generating circuit comprises:

generating means for generating a logical pattern of
correlated peak in a delay profile of a transmission path; and

15   removing means for removing a power component of the
detected correlated peak from the delay profile using the logical
pattern of the correlated peak generated by the generating means.

According to the second aspect of the present invention,
a multi-path detection circuit for detecting a timing of

20   multi-path by measuring a delay profile of a transmission path,
comprises

generating means for generating a logic pattern of a
correlated peak in the delay profile; and

detection means for detecting position of the correlated

25   peak on the basis of the logical pattern of the correlated peak

- 4 -

generated by the generating means.

According to the third aspect of the present invention, a multi-path detection circuit comprises:

a matched filter outputting a correlated value of a spread
5   code and a received signal;

delay profile storing means for storing a delay profile of a transmission path measured by the matched filter;

maximum value retrieving means for retrieving a maximum peak position and a peak level from the delay profile stored
10   in the delay profile storing means;

pattern generating means for sequentially generating logical patterns of correlated peaks on the basis of the leak level and peak position obtained from the maximum value retrieving means; and

15   preparing means for preparing a profile removed a correlation power of the peak retrieved at preceding time by the maximum value retrieving means;

the maximum peak value and the peak level being retrieve sequentially from the profile generated by the generating means.

20   According the forth aspect of the invention, a multi-path detection method for detecting a timing of multi-path by measuring a delay profile of a transmission path, comprises the steps of:

generating a logical pattern of a correlated peak in a
25   delay profile; and

detecting a position of correlated peak on the basis of the generated logical pattern of the correlated peak.

Namely, the multi-path detection circuit according to the present invention is to improve path detection accuracy in the environment where the path is located close in the extent of one chip in the multi-path detection circuit of CDMA type receiver unit.

Therefore, a multi-path detection circuit has generating means for generating a logic pattern of a correlated peak in the delay profile, and removing means for removing a power component of the detected correlated peak from the delay profile using the logical pattern of the correlated peak generated by the generating means.

More particularly, the multi-path detection circuit according to the present invention, has a matched filter outputting a correlated value of a spread code and a received signal, delay profile storing means for storing a delay profile of a transmission path measured by the matched filter, maximum value retrieving means for retrieving a maximum peak position and a peak level of the first correlated peak from the delay profile stored in the delay profile storing means, pattern generating means for generating logical patterns (logical shape) of the first correlated peak on the basis of the leak level and peak position of the first correlated peak obtained from the maximum value retrieving means, and a substractor

substracts the logical pattern of the first correlated peak from the delay profile data stored in the delay profile storage portion upon detecting the second correlated peak.

With raking the construction set forth above, a profile
5   removed the correlated power of the first correlated peak is prepared by the substractor upon detecting the second correlated peak to store in the delay profile storage portion. Subsequently, the maximum value retrieving portion outputs the maximum peak position and the peak level to obtain the peak
10 level and the peak position of the second correlated peak. The pattern generating portion generates the logical pattern of the second correlated peak on the basis of the peak level and the peak position of the second correlated peak.

The substractor subtracts the logical pattern of the
15 second correlated peak from the delay profile data stored in the delay profile storage portion to generate a profile removed the correlated power of the second correlated peak to store. The foregoing operation is counted by the counter to repeat for a predetermined number to retrieve a plurality of correlated
20 peak.

Accordingly, even when the interval of the correlated peaks (path) is narrow to cause overlap on the delay profile, the multi-path can be precisely separated into each individual path to enable detection of the correlated peak position to
25 improve reception performance.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be understood more fully from the detailed description given hereinafter and from the accompanying drawings of the preferred embodiment of the present invention, which, however, should not be taken to be limitative to the invention, but are for explanation and understanding only.

In the drawings:

Fig. 1 is a block diagram showing a construction of one embodiment of a multi-path detection circuit according the present invention;

Fig. 2 is a block diagram showing a construction of one embodiment of a CDMA receiver unit according to the present invention;

Fig. 3 is a block diagram showing an example of a construction of a maximum value retrieving portion of Fig. 1;

Fig. 4 is a block diagram showing an example of a pattern generating portion of Fig. 1;

Fig. 5A is an illustration showing a delay profile in case of one path;

20   invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The present invention will be discussed hereinafter in detail in terms of the preferred embodiment of the present invention with reference to the accompanying drawings. In the

25   following description, numerous specific details are set forth

in order to provide a thorough understanding of the present invention. It will be obvious, however, to those skilled in the art that the present invention may be practiced without these specific detailed. In the other instance, well known

5   structure are not shown in detail in order to avoid unnecessary obscurity of the present invention.

Fig. 1 is a block diagram showing a construction of one embodiment of a multi-path detection circuit according to the present invention. As shown in Fig. 1, the shown embodiment

10 of the multi-path detection circuit 1 is constructed with a matched filter 11, a delay profile storage portion 12, a maximum value retrieving portion 13, a pattern generating portion 14, a subtractor 15 and a counter 16.

The multi-path detection circuit 1 has the matched filter

15 11 outputting a correlation value of a spread code and a received signal. A delay profile of a propagation path (not shown) measured by the matched filter 11 is fed to the delay profile storage portion 12 to be stored therein.

A first correlated peak (path) can be obtained by

20 outputting a maximum peak position and a peak level from the delay profile by the maximum value retrieving portion 13. The pattern generating portion 14 generates a logical pattern of the first correlated peak on the basis of the peak level and the peak position of the first peak obtained from the maximum

25 value retrieving portion 13,

Upon detecting the second correlated peak, the subtractor 15 subtracts the logical pattern of the first correlated peak from the delay profile data in the delay profile storage portion 12 to prepare a profile removing a correlated power of the first

5 correlated peak and stores the prepared profile in the delay profile storage portion 12. It should be noted that the subtractor 15 may be replaced with other means, such as shift register or the like as long as the profile removed the correlated power of the first correlated peak can be generated.

10 Thereafter, the maximum value retrieving portion 13 outputs the maximum peak position and the peak level to obtain the peak level and the peak position of the second correlated peak. The pattern generating portion 14 generates the logical pattern (logical shape) of the second correlated peak on the

15 basis of the peak level and the peak position of the second correlated peak.

The subtractor 15 subtracts the logical pattern of the second correlated peak from the delay profile data stored in the delay profile storage portion 12 to prepare the profile

20 removed the correlated power of the second correlated peak. Then, the prepared profile is stored in the delay profile storage portion 12.

By repeating the foregoing operation for number of times to be measured by the counter 16, a plurality of correlated

25 peak can be retrieved. Accordingly, even if the multi-path

having narrow interval between adjacent correlated peaks to cause overlapping on the delay profile, the multi-paths can be separated into respective of the correlated peaks with high precision to enable detection of the correlated peak position.

5   Thus, reception performance can be improved.

Fig. 2 is a block diagram showing one embodiment of the CDMA receiver according to the present invention. In Fig. 2, one embodiment of the CDMA receiver according to the present invention is constructed with an antenna portion 2, a high

10   frequency reception circuit portion (radio portion) 3, an analog-to-digital (A/D) converter 4, a RAKE finger portion 5, a RAKE synthesizing portion 6 and the multi-path detection circuit 1. The multi-path detection circuit 1 has the construction as shown in Fig. 1. The high frequency reception

15   circuit portion 3 is provided with a channel filter 3a to be used for band restriction with a not shown base station.

The data transmitted as radio wave is received by the antenna portion 2, then is subjected to frequency conversion (down conversion) by the high frequency reception circuit

20   portion 3 and is converted from the analog signal into digital signal by the A/D converter 4.

The signal from the A/D converter 4 is supplied to the multi-path detection circuit 1 for measuring the delay profile of a transmission path and timing of the multi-path is detected.

25   The output of the multi-path detection circuit 1 is used as

a reception timing input of the RAKE finger portion 5. Data received at respective timing are synthesized by the RAKE Synthesizing portion 6.

The multi-path detection circuit 1 has the matched filter 11 outputting the correlated value of the spread code and the received signal. By this, the measured delay profile of the transmission path is stored in the delay profile storage portion 12.

The first correlated peak (path) can be obtained by outputting a maximum peak position and a peak level from the delay profile by the maximum value retrieving portion 13. The pattern generating portion 14 generates a logical pattern of the correlated peak on the basis of the peak level and the peak position of the first correlated peak obtained from the maximum value retrieving portion 13. At this time, the reference pattern (peak shape of one path of the peak level 1) used in the logical pattern of the correlated peak can be arithmetically derived on the basis of a coefficient used in the channel filter 3a. From the reference pattern, the logical pattern of the correlated peak is generated on the basis of the peak level and the peak position of the correlated peak.

Upon detecting the second correlated peak, the subtractor 15 subtracts the logical pattern of the first correlated peak from the delay profile data in the delay profile storage portion 12 to prepare a profile removing a correlated power of the first

correlated peak and stores the prepared profile in the delay profile storage portion 12.

Thereafter, the maximum value retrieving portion 13 outputs the maximum peak position and the peak level to obtain the peak level and the peak position of the second correlated peak. The pattern generating portion 14 generates the logical pattern of the second correlated peak on the basis of the peak level and the peak position of the second correlated peak.

The subtractor 15 subtracts the logical pattern of the second correlated peak from the delay profile data stored in the delay profile storage portion 12 to prepare the profile removed the correlated power of the second correlated peak. Then, the prepared profile is stored in the delay profile storage portion 12. By repeating the foregoing operation for number of times, a plurality of correlated peak can be retrieved. It should be noted that the number of times is measured by the counter 16.

Fig. 3 is a block diagram showing a construction of the maximum value retrieving portion 13 of Fig. 1. In Fig. 3, the maximum value retrieving portion 13 is constructed with a level comparing portion 13a, a selector 13b, a buffer portion(D) 13c and a maximum position storage portion 13d.

The level comparing portion 3a compares the samples of the delay profile data with the interim maximum value in the retrieved samples. The selector 13b selects the same sample

of the delay profile data or the interim maximum value depending
upon the result of compariseon of the level comparing portion
3a.

The buffer portion 13c holds an interim maximum value
5   during maximum value retrieval. The maximum position storage
portion 13d holds a sample position when the level comparing
portion 13a detects new maximum value to output the maximum
peak position. In the construction set forth above, all samples
of the delay profile data are retrieved sequentially. At the
10   end of search, the maximum value among all samples is stored
in the buffer portion 13c.

Fig. 4 is a block diagram showing a construction of the
pattern generating portion 14 of Fig. 1. In Fig. 4, the pattern
generating portion 14 is constructed with a logical pattern
15   memory 14a, a multiplier 14b and a peak position setting portion
14c.

The logical pattern memory 14a holds a preliminarily set
reference pattern. The multiplier 14b sets a peak level using
the reference pattern stored in the logical pattern memory 14a.
20   The peak position setting portion 14c sets the position of the
correlated peak from a peak position input and a peak shape
output (logical pattern) from the multiplier 14b.   The
multiplier 14b may be any other means, such as adder or the
like as long as the peak level can be set using the reference
25   pattern.

The logical pattern memory 14a may be realized by storing the reference pattern indicative of the logical pattern of the correlated peak [the peak shape upon one path as shown in Fig. 7A] as set at peak level 1 in read-only-memory (ROM) or the
5 like.

By removing the power of the detected peak obtained by the pattern generating portion 14, detection of the next correlated peak becomes possible. A timing information of the multi-path thus obtained is supplied to the RAKE finger portion
10 5.

With the construction set forth above, as shown in Fig. 5C, even in multi-path environment where the path interval is narrow to cause overlap of the delay profile, the correlated peak position can be detected with high precision to improve
15 reception performance.

It should be noted that the matched filter 11 is well known to those skilled in the art as means for measuring the delay profile. Therefore, detailed description therefor will be omitted for keeping the disclosure simple enough to facilitate
20 clear understanding of the present invention. It should be noted that a sliding correlator may also be employed in place of the matched filter 11. Similarly, the RAKE finger portion 5 and the RAKE synthesizing portion 6 are well known to those skilled in the art, and are not directly related to the present invention.
25 Therefore, detailed description therefor will be omitted for

keeping the disclosure simple enough to facilitate clear understanding of the present invention.

Figs. 5A to 5C are illustration showing examples of the delay profiles. Fig. 5A shows the delay profile in case of one

5   path. Fig. 5B shows the delay profile in the case where interval between three paths is relatively wide. Fig. 5c shows the delay profile in the case where interval between three paths is narrow.

Fig. 6 is a flowchart showing operation of the multi-path detection circuit 1 of Fig. 1, and Figs. 7A to 7C are illustration

10   showing operation images of respective process for the delay profile data stored in the delay profile storage portion 12. It should be noted that the operation shown in Fig. 6 is realized by executing a program of a not shown control memory by the multi-path detection circuit 1. As the control memory, ROM,

15   integrated circuit (IC) memory and so forth may be used.

With reference to Figs. 1 to 7C, operation of one embodiment of the present invention will be discussed. Here, discussion will be given for the case where the path interval is narrow and delay profiles of a plurality of correlated peaks overlap

20   as shown in Fig.5C.

Fig. 5A shows an example of the correlated peak in the case where only one path is present and only one correlated peak is present. The shape of the correlated peak has a width by a reception filter characteristics.

25   Fig. 5B shows an example of the delay profile in which

three correlated peaks are present with interval about two chips. When the correlated peaks have sufficient interval as shown, presence of the three correlated peaks is definite.

Fig. 5C shows an example of the case in which three correlated peaks are present with interval about one chip. Since respective paths overlap to make respective peak position indefinite. Therefore, accurate detection of the position of the correlated peak is difficult in the conventional method.

Next, discussion will be given for operation of the multi-path detection circuit 1. In the multi-path detection circuit 1, at first, the counter 16 counting number of detected peaks is reset (step S1 of Fig. 6). Subsequently, in the multi-path detection circuit 1, the delay profile is measured by the matched filter 11 (step S2 of Fig. 6). An example of the delay profile measured by the matched filter 11 is shown in Fig. 7A.

Thereafter, maximum value retrieval is performed by the maximum value retrieving portion 13 (step S3 of Fig. 6). The maximum value retrieving portion 13 outputs the detected path timing (correlated peak position) to the RAKE finger portion 5 (step S4 of Fig. 6). The pattern generating portion 14 generates the logical pattern [see Fig. 7B] of the detected peak on the basis of the maximum value and the peak position information detected by the maximum value retrieving portion 13 (step S5 of Fig. 6).

The subtractor 15 subtracts the logical pattern generated by the pattern generating portion 14 from the delay profile data [see Fig. 7c] to remove the power component of the detected peak from the delay profile data (step S6 of Fig. 6).

5   The delay profile storage portion 12 stores data removed the power component of the detected peak from the delay profile data by the subtractor 15 (step S7 of Fig. 6). After completion of this process, the counter 16 is counted up (step S8 of Fig. 6). By repeating the foregoing process for the times
10   corresponding to number of fingers (step S9 of Fig. 9), necessary number of peaks can be detected.

As set forth above, even in the multi-path environment where the correlated peaks of the delay profiles are overlapped , the multi-path detection circuit 1 can detect timing of
15   respective path at high precision. Therefore, reception performance can be improved.

Fig. 8 is a block diagram showing a construction of the maximum value retrieving portion of another embodiment of the multi-path detection circuit according to the present invention.
20   In Fig. 8, another embodiment of the present invention has the same construction as the maximum value retrieving portion 13 in the former embodiment of the present invention shown in Fig. 3 except for a coefficient multiplying portion 71 is provided in the maximum value retrieving portion 7. Like components to
25   those in the former embodiment will be identified by like

reference numerals and detailed description therefor will be omitted for avoiding redundant discussion and whereby to keep the disclosure simple enough to facilitate clear understanding of the present invention.

5   It should be noted that the basic construction of another embodiment of the multi-path detection circuit according to the present invention is the same as the construction of the multi-path detection circuit in the former embodiment shown in Fig. 1. Therefore, detailed description therefor will be

10   omitted for avoiding redundant discussion and whereby to keep the disclosure simple enough to facilitate clear understanding of the present invention.

In Fig. 8, the maximum value retrieving portion 7 is constructed with the level comparing portion 13a, the selector

15   13b, buffer portion 13c, maximum position storage portion 13d and coefficient multiplying portion 71.

The level comparing portion 13a compares the sample of the delay profile data with the interim maximum value in the retrieved samples. The selector 13b selects the sample of the

20   delay profile data and the interim maximum value depending upon the result of comparison of the level comparing portion 13a. The buffer portion 13c stores the interim maximum value during maximum value retrieval.

In the construction set forth above, all sample of the

25   delay profile data is retrieved sequentially. At the end of

search, the maximum value among all samples is stored in the

buffer portion 13c. The maximum position storage portion 13d

holds a sample position when the level comparing portion 13a

detects new maximum value to output the maximum peak position.

5   Here, the coefficient multiplying portion 71 multiples

the maximum value among all samples stored in the buffer portion

13c with a preliminarily set given value α to output the product

to the level comparing portion 13a and the selector 13b.

        By this, upon detection of the maximum value, when a

10   plurality of sample points having equivalent level as the maximum

correlation level are present, the sample having the least delay

period (left side of the delay profile) among these samples

can be selected as maximum point of the samples (left side of

the delay profile). It should be noted that coefficient

15   multiplying portion 71 may be replaced with adder or the like

as long as the sample having the least delay period can be taken

as the maximum point.

        Fig. 9 is a flowchart showing operation of another

embodiment of the multi-path detection circuit according to

20   the present invention. Figs. 10A to 10C show example of process

operation by another embodiment of the present invention.

Operation and effect of another embodiment of the multi-path

detection circuit according to the present invention will be

discussed with reference to Figs. 8 to 10C.

25   It should be noted that the basic construction of another

embodiment of the multi-path detection circuit according to the present invention is the same as the former embodiment of the multi-path detection circuit and the CDMA receiver shown in Fig.1 and Fig.2 according to the invention. Therefore, Like

5 components to those in the former embodiment will be identified by like reference numerals and detailed description therefor will be omitted for avoiding redundant discussion and whereby to keep the disclosure simple enough to facilitate clear understanding of the present invention. ON the other hand, the

10 operation shown in Fig. 9 is realized by executing a program in the not shown control memory by the multi-path detection circuit 1. As the control memory, ROM, IC memory or the like may be used.

Here, discussion will be given for the case where the

15 path interval is narrow and delay profiles of a plurality of correlated peaks overlap as shown in Fig. 5C. Fig. 5C shows an example of the case in which three correlated peaks are present with interval about one chip. Since respective paths overlap to make respective peak position indefinite. Therefore,

20 accurate detection of the position of the correlated peak is difficult in the conventional method.

In the multi-path detection circuit 1, at first, the counter 16 counting number of detected peaks is reset (step S11 of Fig. 9). Subsequently, in the multi-path detection circuit

25 1, the delay profile is measured by the matched filter 11 (step

S12 of Fig. 9).

Thereafter, maximum value retrieval and maximum position retrieval are performed by the maximum value retrieving portion 7 (steps S13 and S14 of Fig. 9). The maximum value retrieving

5 portion 7 outputs the path timing (correlated peak position) to the RAKE finger portion 5 (step S15 of Fig. 9). The pattern generating portion 14 generates the logical pattern of the detected peak on the basis of the maximum value and the peak position information detected by the maximum value retrieving

10 portion 7 (step S16 of Fig. 9).

The subtractor 15 subtracts the logical pattern generated by the pattern generating portion 14 from the delay profile data to remove the power component of the detected peak from the delay profile data (step S17 of Fig. 9). The delay profile

15 storage portion 12 stores data removed the power component of the detected peak from the delay profile data by the subtractor 15 (step S18 of Fig. 9). After completion of this process, the counter 16 is counted up (step S19 of Fig. 9). By repeating the foregoing process for the times corresponding to number

20 of fingers (step S20 of Fig. 9), necessary number of peaks can be detected.

As set forth above, even in the multi-path environment where the correlated peaks of the delay profiles are overlapped, the multi-path detection circuit 1 can detect timing of

25 respective path at high precision. Therefore, reception

performance can be improved.

Fig. 10A shows an example of the delay profile in which a plurality of paths are located close proximity and levels of respective paths are substantially equal. In this case, in the maximum value retrieving portion 13 of the one embodiment of the present invention, difficulty is encountered in making judgment which sample is to be the first correlated peak, In contrast to this, in the maximum value retrieving portion 7 of the shown embodiment, as the peak of the profile, the point at the left most position (detecting position 1) can be sleeted.

Therefore, the procedure shown in Figs. 10B and 10C, namely by the procedure, in which the first peak component is removed from the delay profile to detect the detecting position 2, and subsequently the second peak component is removed from the delay profile to detect the detecting position 3, the power component of the detected peak is removed per one peak to separate all multi-path components to perform detection.

It should be noted that while the shown embodiment is designed to detect the peak located at the leftmost position, namely have the least delay period, as the profile peak sequentially, it is also possible to detect the peak located at the rightmost position, namely the peak having the most delay period as the profile peak for detecting the profile peaks sequentially by inverting the scanning direction.

Fig. 11 is a block diagram showing a further embodiment

of the multi-path detection circuit according to the present invention. In Fig. 11, the further embodiment of the multi-path detection circuit 8 according to the present invention has the same construction as one embodiment of the multi-path detection

5   circuit 1 shown in Fig. 1 except for presence of a path interval judgment portion 82 and a sample subtractiong portion 83. Like components to those in the former embodiment will be identified by like reference numerals and detailed description therefor will be omitted for avoiding redundant discussion and whereby

10   to keep the disclosure simple enough to facilitate clear understanding of the present invention. Also, operations of the common components are the same as those in one embodiment of the invention. It should be noted that, in the multi-path detection circuit 8, a detection objective pattern generating

15   portion 81 is formed by the pattern generating portion 14 and the subtractor 15.

The path interval judgment portion 82 makes judgment of interval of the path timing on the basis of the path timing output from the maximum value retrieving portion 13, to drive

20   the detection objective pattern generating portion 81 when the interval of the path timing becomes smaller than a preliminarily set interval, and to drive the sample detecting portion 83 when the interval of the path timing becomes greater than the preliminarily set interval. It should be noted that the path

25   interval judgment portion 82 outputs the path timing output

from the maximum value retrieving portion 13 as is out of the multi-path detection circuit 8.

The pattern generating portion 14 and the subtractor 15 in the detection objective pattern generating portion 81 perform generating operation of the delay profile data to be an object for detection. On the other hand, the sample detecting portion 83 performs similar operation as the prior art. IN the further embodiment of the present invention, pattern generating operation by the pattern generating portion 14 and the subtractor 15 is performed only for the multi-path, in which the delay profiles overlap.

Fig. 12 is an illustration showing one example of the reference pattern to be used in the pattern generating portion in the further embodiment of the present invention. In the delay profile, before and after the wave representative of the profile peak of one path, side lobe is generated to make interval between the correlated peak narrower to cause overlap of the delay profile, these side lobe may be included in the waveform.

Therefore, in the further embodiment of the present invention, upon generation of the reference pattern, the side lob portion is preliminarily prepared together with the profile peak to store as shown in Fig. 12. By this, the side lobe portion can be eliminated from the profile peak including the side lobe of adjacent profile. Thus, more accurate detection of the multi-path component becomes possible.

As set forth above, according to the present invention, in the multi-path detection circuit detecting the timing of the multi-path, the logical shape of the correlated peak in the delay profile is generated for detecting the correlated

5   peak on the basis of the generated logical shape of the correlated peak to enhance precision in detection of the path timing in the multi-path environment where the correlated peaks overlap on the delay profile, to obtain better reception performance.

Although the present invention has been illustrated and

10   described with respect to exemplary embodiment thereof, it should be understood by those skilled in the art that the foregoing and various other changes, omission and additions may be made therein and thereto, without departing from the spirit and scope of the present invention. Therefore, the

15   present invention should not be understood as limited to the specific embodiment set out above but to include all possible embodiments which can be embodied within a scope encompassed and equivalent thereof with respect to the feature set out in the appended claims.

20
